

Random Numbers Notes

Reflection Note: 1

Random Numbers

What I learned about random numbers

```
#include <iostream>
#include <cstdlib>

int main() {
    int n = rand(); // why is this the same number every re-compile?

    std::cout << "Your random number: " << n << std::endl;
    std::cout << "Random Max: " << RAND_MAX << std::endl;
    std::cout << "Real Random generated: [1] " << (rand() % 10) << std::endl;
    std::cout << "Real Random generated: [2] " << (rand() % 10) << std::endl;
    std::cout << "Real Random generated: [3] " << (rand() % 10) << std::endl;
    return 0;
}
```

what I've learned is that, `rand()` is not so random when assigned to a variable.

lol... what I mean is doing: `int n = rand();` - whatever that value for `n` is that shit is going to stay that value **every** re-compile.

however, an interesting thing is when we look at:

```
std::cout << (rand() % 10) << std::endl;
// hell even when we just do...
std::cout << (rand()) << std::endl // it will be a random number
```

So what I'm implying is `rand()` is not so weird, but it's not truly a random number generator?
